Abstract: A total synthesis of (+)-conolidine has been achieved via the gold(I)-catalyzed cascade cyclization of a conjugated enyne. Remarkably, this strategy allowed for the simultaneous formation of the indole ring and the ethylidene-substituted piperidine moiety of (+)-conolidine under homogenous gold catalysis in an enantioselective manner (88–91% ee).

Conolidine (**1**), which belongs to the C5-nor stemmadenine family of alkaloids, was first isolated from *Tabernaemontana divaricata* by Kam *et al.* in 2004 (Figure 1).¹ This group only managed to isolate 0.0013 g of conolidine from the stem bark of this small flowering plant. Since Bohn, Micalizio, and co-workers accomplished the first asymmetric total synthesis of conolidine (**1**) in 2011, there has been considerable interest in its unique analgesic activity, which differs from that of many common opioids, including morphine.² Although several efficient methods have been reported for the synthesis of C5-nor stemmadenine-type indoles,^{2–4} the development of a diversity-oriented route suitable for evaluating the structure-activity relationships of these compounds is still highly desired.

Homogeneous gold catalysis has attracted considerable attention because of the strong π -acidity of gold, as well as its potential to stabilize cationic reaction intermediates.⁵ The versatile reactivity of gold catalysts has allowed for the design of several eloquent cascade reactions for the direct step- and atom-economical synthesis of complex molecules.⁶ Nowadays, homogeneous gold catalysis is recognized as one of the most effective strategies for the electrophilic activation of alkynes for the synthesis of natural products.^{6f}

We recently reported the gold(I)-catalyzed bis-cyclization of conjugated diynes **2** ($R' = H$, $-NuH = CH_2OH$) as an efficient strategy for the construction of fused indoles **3** and **4** (Scheme 1).⁷ In this reaction, the initial indole formation occurred via a *5-endo-dig* cyclization, which was followed by a *7-endo-dig* cyclization to give the fused indole **3** as the major product. Based on this reaction, we designed a strategy for the synthesis of (+)-conolidine (**1**) (Scheme 2, strategy I). It was envisaged that the known conolidine precursor **7**^{2,4} could be prepared by the gold(I)-catalyzed cascade cyclization of conjugated diyne **10**. In this sense, the bis-cyclization reaction would allow for the formation of a fused indole (path a and b), which would be followed by a third cyclization to give the piperidine moiety. One of the potential issues with this strategy would be controlling the regioselectivity of the second cyclization step. In particular, the *6-exo-dig* cyclization (path b) would need to be favored over the *7-endo-dig* pathway (path b') to allow for the introduction of the oxygen atom at the appropriate carbon of the product. We also designed a second strategy (strategy II) using a conjugated enyne **11** bearing a silyl enol ether.⁸ Notably, this strategy would avoid the need to control the regioselectivity of the second cyclization described in strategy I by introducing the oxygen atom of the conolidine as a silyl ether. It was also envisaged that the nucleophilicity of

the enol ether would be increased following the formation of the indole, leaving it better equipped to promote the subsequent formation of the piperidine ring. Furthermore, the use of a chiral auxiliary (in strategy I) or chiral gold complex would allow for the asymmetric induction of these key steps. Both of these strategies involve the use of readily accessible synthons **12–16**, and can therefore be considered as diversity-oriented convergent syntheses. Herein, we report the total synthesis of (+)-conolidine (**1**) based on the catalytic asymmetric cyclization of the enol ether-type substrate **11** (strategy II).

Scheme 1. Previous Work: Gold(I)-Catalyzed Intra-molecular Consecutive Cyclizations of a Conjugated Diyne

Scheme 2. Retrosynthetic Analysis of Conolidine Based on the Gold(I)-Catalyzed Cascade Reaction of Conjugated Alkynes

Strategy I. We initially conducted a series of model experiments using conjugated diynes **2a–c** to evaluate the possibility of controlling the regioselectivity in strategy I (Scheme 3). The reaction of **2a** bearing a phenylglycinol moiety gave the desired isomer **4a** as a minor product (**4a/3a** = 29:71). In contrast, substrate **2b** bearing a vicinal phenyl group and substrate **2c** bearing a carboxylic acid preferentially afforded the corresponding 6-*exo*-products (**4/3** = 71:29–80:20). Based on these results, we prepared the corresponding alcohol and carboxylic acid substrates **10a** and **10b** as the most suitable candidates for the synthesis of conolidine.

Scheme 3. Model Experiment for Control of the Regioselectivity in the Second Cyclization

^a The *erythro*-isomer of (±)-**2b** was used.

Our initial efforts towards the preparation and subsequent gold(I)-catalyzed cyclization of the conjugated diynes **10a** and **10b** are shown in Scheme 4. The alkylation of tosylamide **17**⁹ with 1-bromobut-2-yne (**18**) gave diyne **19**. The iodination of the terminal alkyne moiety in **19** with NIS and AgNO₃, followed by the subsequent Cadiot–Chodkiewicz coupling¹⁰ of the resulting iodoalkyne with **13a** or **13b** gave the amino alcohol- and amino acid-type substrates (±)-**10a** and **10b** (after hydrolysis), respectively. Unfortunately, however, the subsequent reaction of **10a** with IPrAuCl/AgOTf (10 mol %) and EtOH (2 equiv) in 1,2-DCE at 50 °C for 2 h gave a complex mixture of unidentified products. In contrast, the reaction of **10b** under the same conditions led to the formation of the bis-cyclization products **20b** and **20b'** with good regioselectivity for the former of these two products (**20b/20b'** = 90/10). It is noteworthy, however, that these compounds were formed in low yields (<31%) because of their poor stability. Disappointingly, all of our other attempts to promote the formation of the piperidine using **10b** and **20b/20b'** resulted in failure, most likely because of the poor nucleophilicity of the enol ether moiety of **20b** bearing an electron-withdrawing group. Based on these results, we discarded strategy I and focused our efforts on strategy II using the conjugated enynes **11a** and **11b**.

Scheme 4. Unsuccessful Attempts at the Gold(I)-Catalyzed Cyclization of the Conjugated Diynes **10a** and **10b** (Strategy I)

Strategy II. Conjugated enynes **11a** and **11b** bearing different silyl enol ether moieties were prepared according to route shown in Scheme 5. The alkylation of tosylamide **21**¹¹ with ethyl 4-bromobutanoate (**22**) gave ester **23**, which was reduced with DIBAL to give the corresponding aldehyde. The subsequent 1,2-addition of lithium (trimethylsilyl)acetylide (**15**) to this aldehyde, followed by the removal of the TMS group with TBAF afforded the terminal alkyne **25** in excellent yield. The Sonogashira coupling reaction of alkyne **25** with *o*-iodoaniline (**16**) provided alkynylaniline **26** in 90% yield. The oxidation of **26** with MnO_2 gave the corresponding ketone **27** in 71% yield, which was treated with TIPSOTf or TBSOTf in the presence of Et_3N to give the conjugated enyne-type silyl enol ethers **11a** and **11b** in 75 and 81% yields, respectively. It is noteworthy that the (*E*)- and (*Z*)-isomers¹² of **11** could be separated, as necessary, by column chromatography over silica gel followed by PTLC (see Supporting Information).

Scheme 5. Preparation and Gold-Catalyzed Cyclization of the Conjugated Enynes **11a** and **11b**

We then investigated the gold(I)-catalyzed cascade reaction of the enol ether-type conjugated enynes **11a** and **11b** (Table 1). The treatment of enyne **11a** with **L1**Au(MeCN)SbF₆ (5 mol %) (Figure 2) in toluene-*d*₈ at room temperature afforded the desired product **9** (16%), as well as the two monocyclization products **28**¹³ (34%) and **29** (14%). To drive the reaction to completion, we investigated the use of an additive as a proton source as well as silyl scavenger. Fortunately, the addition of H₂O⁴ improved the yields of **9** to 38% (entry 2). In contrast, the use of MeOH was less efficient (entry 3). The use of an IPr ligand was found to be unsuitable for this reaction (entry 4). Similarly, several other experiments using NaBARF^{8h} (Figure 2) as the counter anion (entry 5), CD₂Cl₂ as a solvent (entry 6) or the TBS ether **11b** as a substrate (entry 7) did not improve the yield.

^a Unless otherwise noted, all of these reactions were carried out using **11a** (*Z/E* = 79:21) or **11b** (*Z/E* = 71:29) with **L1**Au(MeCN)SbF₆ or IPrAuCl (5 mol %)/AgSbF₆ (5 mol %) in toluene-*d*₈ (0.2 M) at room temperature in the presence of an additive (1.5 equiv). ^b NMR yields were evaluated using mesitylene as an internal standard. ^c Using **L1**AuCl/NaBARF. ^d Using CD₂Cl₂ as a solvent instead of toluene-*d*₈.

Figure 2. Ligands and co-catalysts screened in this study

We then proceeded to investigate the enantioselective gold(I)-catalyzed cascade reaction of the conjugated enyne **11a** (Table 2). Based on a related study reported by Toste and co-workers involving the asymmetric carbocyclization of a silyl enol ether,^{8h} we investigated the use of biarylphosphine-type dinuclear chiral gold complexes to affect this reaction (Figure 2). The treatment of the conjugated enyne **11a** with (*R*)-DTBM-SEGPHOS(AuCl)₂ (5 mol %)/AgSbF₆ (10 mol %) resulted in the formation of the undesired ketone **29** as the major product (entry 1). The use of (*R*)-MeO-DTBM-BIPHEP gave the desired product (*S*)-**9** in 13% yield and 89% ee (entry 2). An increase in catalyst loading (10 mol % for the bimetallic gold complex) led to a slight decreased in the yield to 10%, as well as a decrease in the ee to 76% (entry 3). Expecting that the sterically less hindered (*Z*)-isomer has better reactivity, we examined the reaction of the both isomers, (*Z*)- and (*E*)-**11a**. Interestingly, the use of (*Z*)-**11a** led to an improvement in the yield of (*S*)-**9** to 32% (entry 5), whereas the reaction of (*E*)-**11a** failed to afford the desired product (entry 4). Taken together,

these results suggested that it was only possible to generate the desired product **9** from the *Z*-isomer of **11a** when a *E/Z* mixture of **11a** was used as the substrate (entries 1–3). The use of **11a** in conjunction with a decreased loading of H₂O (1.0 equiv) led to an improvement in the ee to 91%, although the yield dropped to 18% (entry 6).

^a Unless otherwise noted, these reactions were carried out using **11a** in toluene (0.2 M) at room temperature in the presence of H₂O (1.5 equiv) with a catalyst loading of 5 (for the bimetallic gold complex) and 10 mol % (for AgSbF₆). ^b Isolated yields. ^c Determined by chiral HPLC. ^d Ketone **29** was obtained as the major product. ^e N.D. = not detected. ^f The catalyst loading was increased to 10 and 20 mol %. ^g Using H₂O (1.0 equiv).

Finally, we investigated the conversion of the bis-cyclization product (*S*)-**9** (91% ee) to (+)-conolidine (**1**). The treatment of (*S*)-**9** with Na/naphthalene resulted in the cleavage of the Ts protecting group to give the known conolidine precursor **7** in 60% yield (Scheme 6). According to the procedure reported by Bohn, Micalizio, and co-workers,² we obtained (+)-conolidine (**1**) in 34% yield and 84% ee. The spectroscopic and specific optical rotation data for the synthetic conolidine were identical to those reported in the literature.^{1,2}

Scheme 6. Total Synthesis of (+)-Conolidine

In conclusion, we have achieved the total synthesis of (+)-conolidine based on the gold(I)-catalyzed cascade cyclization of a conjugated enyne. This study has shown that the feasibility of catalytic asymmetric reactions involving chiral gold(I) complexes for the construction of stemmadenine-type scaffolds.

Experimental Section

General Methods. For open column chromatography, silica gel or NH_2 silica gel was employed. Thin layer chromatography was performed on TLC silica gel 60 F₂₅₄ or NH_2 silica gel 60 F₂₅₄ plate (layer thickness 0.25 mm), which were developed using standard visualizing agents: UV fluorescence (254 nm) and anisaldehyde with heating. Melting points were measured by a hot stage melting point apparatus (uncorrected). In ^1H NMR spectra, chemical shifts are reported in δ (ppm) relative to TMS as internal standard. In ^{13}C NMR spectra, chemical shifts are referenced to the residual solvent signal. ^1H NMR spectra are tabulated as follows: chemical shift, multiplicity (b = broad, s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet), number of protons, and coupling constant(s).

The compounds **16**, **18**, **22**, and (*R*)-DTBM-SEGPHOS(AuCl)₂ were obtained commercially and used without further purification. The known compounds **S1**,¹⁴ **S4**,¹⁵ **S7**,¹⁶ **17**,⁹ **21**,¹¹ and (*R*)-MeO-BIPHES(AuCl)₂^{17,18} were prepared according to the literature. Structures of **S1**–**S9** are shown in Schemes S1–S3 (Supporting Information).

Preparation of Starting Materials.

(*R*)-2-Phenyl-2-({2-[(trimethylsilyl)ethynyl]phenyl}amino)ethan-1-ol (S2). The coupling of

S1 and trimethylsilylacetylene was carried out according to the reported method¹⁹ as follows: to a stirred suspension of **S1** (1.42 g, 4.86 mmol), PdCl₂(PhCN)₂ (112 mg, 0.29 mmol) and CuI (55.6 mg, 0.29 mmol) in dry 1,4-dioxane (10 mL) under argon were added diisopropylamine (3.4 mL, 24.2 mmol), trimethylsilylacetylene (0.7 mL, 5.06 mmol) and tri(*tert*-butyl)phosphine (0.2 mL, 0.85 mmol). After stirring at 50 °C for 12 h, the reaction mixture was diluted with EtOAc and filtered through a short pad of silica gel. The filtrate was concentrated *in vacuo* and the residue was chromatographed on silica gel (hexane/EtOAc = 5/1) to afford **S2** (976 mg, 65%) as amber oil: $[\alpha]_D^{29}$ 242 (*c* 0.51, CHCl₃); IR (neat): 3393 (OH), 2143 (C≡C); ¹H NMR (500 MHz, CDCl₃) δ: 0.30 (s, 9H), 1.69 (br s, 1H), 3.80-3.83 (br m, 1H), 3.96-4.00 (br m, 1H), 4.56-4.57 (br m, 1H), 5.52-5.53 (br m, 1H), 6.38 (d, *J* = 8.6 Hz, 1H), 6.57-6.58 (m, 1H), 7.00-7.04 (m, 1H), 7.25-7.35 (m, 6H); ¹³C NMR (125 MHz, CDCl₃) δ: 0.0 (3C), 59.3, 67.3, 100.7, 101.8, 108.0, 110.9, 116.6, 126.5 (2C), 127.6, 128.7 (2C), 129.9, 131.7, 139.7, 148.4; HRMS (FAB) calcd for C₁₉H₂₄NOSi (MH⁺) 310.1622, found 310.1620.

(R)-2-[(2-Ethynylphenyl)amino]-2-phenylethan-1-ol (S3). The desilylation of **S2** was carried out according to the reported method²⁰ as follows: K₂CO₃ (1.08 g, 8.0 mmol) was added to the solution of **S2** (804 mg, 2.60 mmol) in MeOH (26 mL). After stirring at room temperature for 1 h, the mixture was diluted with EtOAc. The organic layer was separated, washed with water and brine, dried over MgSO₄, and concentrated *in vacuo*. The residue was chromatographed on silica gel (hexane/EtOAc = 5/1) to afford **S3** (445 mg, 72%) as pale amber powder: mp 79 °C; $[\alpha]_D^{26}$ 240 (*c* 1.06, CHCl₃); IR (neat): 3401 (OH), 3253 (C≡CH), 2089 (C≡C); ¹H NMR (500 MHz, CDCl₃) δ: 1.66 (dd, *J* = 7.5, 5.2 Hz, 1H), 3.50 (s, 1H), 3.82-3.87 (m, 1H), 3.97-4.03 (m, 1H), 4.60 (dd, *J* = 10.4, 6.4 Hz, 1H), 5.47-5.48 (br m, 1H), 6.39 (d, *J* = 8.7 Hz, 1H), 6.59-6.61 (m, 1H), 7.04-7.06 (m, 1H), 7.27-7.30 (m, 1H), 7.31-7.38 (m, 5H); ¹³C NMR (125 MHz, CDCl₃) δ: 59.4, 67.3, 80.6, 83.3, 106.9, 111.1, 116.8, 126.6 (2C), 127.7, 128.9 (2C), 130.2, 132.6, 139.6, 148.4; HRMS (FAB) calcd for C₁₆H₁₆NO (MH⁺) 238.1226, found 238.1232.

(R)-2-Phenyl-2-[[2-(phenylbuta-1,3-diyn-1-yl)phenyl]amino]ethan-1-ol (2a). The coupling

of **S3** and ethynylbenzene was carried out according to the reported method²¹ as follows: a mixture of **S3** (432 mg, 1.82 mmol), ethynylbenzene (1.0 mL, 9.11 mmol), Cu(OAc)₂·H₂O (36.3 mg, 0.18 mmol) and piperidine (0.5 mL, 5.06 mmol) in CH₂Cl₂ (9 mL) was stirred in open atmospheric air at room temperature for 5 h. The reaction mixture was concentrated *in vacuo* and the residue was chromatographed on silica gel (hexane/EtOAc = 5/1) to afford **2a** (349 mg, 57%) as amber oil: $[\alpha]_D^{26}$ 470 (*c* 1.00, CHCl₃); IR (neat): 3391 (OH), 2208 (C≡C), 2140 (C≡C); ¹H NMR (500 MHz, CDCl₃) δ: 1.71-1.73 (m, 1H), 3.86-3.89 (m, 1H), 3.99-4.04 (m, 1H), 4.60-4.62 (m, 1H), 5.45-5.47 (br m, 1H), 6.38 (d, *J* = 8.1 Hz, 1H), 6.60-6.62 (m, 1H), 7.05-7.07 (m, 1H), 7.27-7.31 (m, 1H), 7.33-7.39 (m, 8H), 7.56-7.57 (m, 2H); ¹³C NMR (125 MHz, CDCl₃) δ: 59.4, 67.2, 74.0, 78.5, 79.7, 83.0, 106.5, 111.3, 117.0, 121.8, 126.6 (2C), 127.7, 128.4 (2C), 128.8 (2C), 129.1, 130.7, 132.4 (2C), 133.4, 139.4, 149.4; HRMS (FAB) calcd for C₂₄H₂₀NO (MH⁺) 338.1539, found 338.1537.

(±)-(1R,2S)-2-[(2-Bromophenyl)amino]-1,2-diphenylethan-1-ol [(±)-S5]. The reaction of 2-bromoiodobenzene and (±)-**S4** was carried out according to the reported method¹⁴ as follows: a mixture of 2-bromoiodobenzene (0.9 mL, 7.01 mmol), (±)-**S4** (1.72 g, 8.06 mmol), NaOH (600 mg, 15.0 mmol), and CuI (35.7mg, 0.19 mmol) was stirred under argon at 90 °C for 13 h. The reaction mixture was diluted with EtOAc, washed water and brine, dried over Na₂SO₄, and concentrated *in vacuo*. The residue was chromatographed on silica gel (hexane/EtOAc = 10/1) to afford (±)-**S5** (2.06 g, 80%) as pale amber powder: mp 100 °C; IR (neat): 3398 (OH), 1321 (NH); ¹H NMR (500 MHz, CDCl₃) δ: 2.37-2.39 (br m, 1H), 4.67-4.69 (m, 1H), 5.06-5.07 (m, 1H), 5.14-5.16 (br m, 1H), 6.35 (d, *J* = 8.0 Hz, 1H), 6.48 (t, *J* = 7.7 Hz, 1H), 6.93 (t, *J* = 7.7 Hz, 1H), 7.11-7.12 (m, 4H), 7.23-7.24 (m, 3H), 7.27-7.28 (m, 3H), 7.35-7.37 (m, 1H); ¹³C NMR (125 MHz, CDCl₃) δ: 64.4, 78.0, 110.5, 112.8, 118.0, 126.5 (2C), 127.1 (2C), 127.7, 128.0, 128.2, 128.3 (2C), 128.6 (2C), 132.2, 139.6, 140.4, 143.9. *Anal.* calcd for C₂₀H₁₈BrNO: C, 65.23; H, 4.93; N, 3.80. (*S,E*)-(3-Ethylidenepiperidin-4-yl)(1*H*-indol-2-yl)methanone (7). According to the reported method,²⁶ removal of the tosyl group was carried out as follows: sodium (27.7 mg, 1.20 mmol) was added to a solution of naphthalene (193 mg, 1.50 mmol) in THF (1.5 mL) at room temperature and the mixture stirred for 30 min. The resulting dark green/blue solution (*ca.* 0.8 M in THF) was added dropwise to a solution of (*S*)-**9** (49.2 mg, 0.12 mmol, 91% ee) in THF (1.2 mL) at 0 °C until dark green/blue color persisted. Saturated aqueous NaHCO_3 was added and the solution was allowed to warm slowly to room temperature. The aqueous layer was then extracted with CH_2Cl_2 and the organic layers were washed with brine, combined, dried over K_2CO_3 and filtered. Concentration under reduced pressure and recrystallization from CH_2Cl_2 –hexane afforded (+)-**7** (18.5 mg, 60%): mp 205–210 °C; $[\alpha]^{28}_{\text{D}} = +41.0$ (c 0.26, MeOH), comparable to the report by Bohn *et. al.* (2011)¹⁶: $[\alpha]^{25}_{\text{D}} = +45.0$ (c 0.24, MeOH); IR (neat): 3345 (NH), 1627 (C=O); ^1H NMR (500 MHz, CDCl_3) δ : 1.72 (dd, $J = 6.9, 1.7$ Hz, 3H), 1.87–1.95 (m, 1H), 2.20–2.22 (br m, 1H), 2.97–3.00 (br m, 1H), 3.15 (ddd, $J = 12.6, 12.6, 2.9$ Hz, 1H), 3.33 (d, $J = 12.6$ Hz, 1H), 3.49 (s, 1H), 3.72 (d, $J = 12.6$ Hz, 1H), 4.53–4.54 (br m, 1H), 5.54 (q, $J = 6.7$ Hz, 1H), 7.15–7.17 (m, 1H), 7.28 (s, 1H), 7.34–7.36 (m, 1H), 7.43 (d, $J = 8.0$ Hz, 1H), 7.71 (d, $J = 8.0$ Hz, 1H), 9.16 (br s, 1H); ^{13}C NMR (125 MHz, CDCl_3) δ : 13.0, 31.5, 43.0, 43.2, 53.1, 108.9, 112.1, 120.8, 121.0, 123.1, 126.3, 127.6, 134.4, 135.1, 137.1, 193.6; HRMS (FAB) calcd for $\text{C}_{16}\text{H}_{19}\text{N}_2\text{O}$ (MH^+) 255.1497, found 255.1490.
